## CONVERSION FACTORS, ABBREVIATIONS, AND VERTICAL DATUM

Multiply	By	To obtain
inch (in.)	2.54	centimeter
cubic inch (in. <sup>3</sup> )	16.39	cubic centimeter
inch (in.)	25,400	micrometer
inch per year (in/yr)	0.02540	meter per year
foot (ft)	0.3048	meter
foot per day (ft/d)	0.3048	meter per day
foot per year (ft/yr)	0.3048	meter per year
foot squared per day (ft <sup>2</sup> /d)	0.09290	meter squared per day
mile (mi)	1.609	kilometer

**Vertical datum:** In this report, “sea level” refers to the National Geodetic Vertical Datum of 1929—a geodetic datum derived from a general adjustment of the first-order level nets of the United States and Canada, formerly called Sea Level Datum of 1929.

**Other abbreviated units of measure:** Water temperature, chemical concentration, and other chemical and physical properties of constituents are given in metric units. Water temperature is given in degrees Celsius ( $^{\circ}\text{C}$ ) and can be converted to degrees Fahrenheit ( $^{\circ}\text{F}$ ) by use of the following equation:

$$^{\circ}\text{F} = 1.8 ( ^{\circ}\text{C}) + 32$$

Chemical concentration in water is expressed in milligrams per liter (mg/L) or micrograms per liter ( $\mu\text{g}/\text{L}$ ).

Molecular weight and other mass expressions are expressed in grams (g), and density is given in grams per cubic centimeter (g/cm<sup>3</sup>). Other abbreviations used include milliliter (mL) or liter (L) for volume measurements and micrometer ( $\mu\text{m}$ ), which equals  $1 \times 10^{-6}$  meter, for length.

Specific conductance is measured in microsiemens per centimeter ( $\mu\text{S}/\text{cm}$ ). Wavelengths are measured in nanometers (nm).

# **Water-Quality and Water-Level Data for a Freshwater Tidal Wetland, West Branch Canal Creek, Aberdeen Proving Ground, Maryland, October 1998–September 1999**

**By Tracey A. Spencer, Lisa D. Olsen, Michelle M. Lorah, and Mastin M. Mount**

## **Abstract**

This report presents water-quality data for ground-water and surface-water samples and water-level data collected by the U.S. Geological Survey from October 1998 through September 1999 at West Branch Canal Creek, Aberdeen Proving Ground, Maryland. The report also provides a description of the sampling and analytical methods that were used to collect and analyze the samples, and includes an evaluation of the quality-assurance data.

The ground-water sampling network includes 88 wells or piezometers, including four 2-inch wells, two 4-inch wells, thirty 0.75-inch piezometers, and fifty-two 0.25-inch piezometers. Water levels were measured in 105 wells or piezometers. Surface-water samples were collected at five sites.

Samples were collected from wells and 0.75-inch piezometers for measurement of field parameters, and analysis of inorganic and organic constituents during three sampling rounds: March, May through June, and July through August of 1999. Inorganic constituents and organic constituents were analyzed in samples collected from 0.25-inch piezometers during three sampling rounds in February through March, May, and September of 1999. Water levels were measured in October and November of 1998, and in February and May of 1999. Surface-water samples were collected between February and August of 1999 for analysis of organic constituents.

## **Introduction**

The U.S. Geological Survey (USGS) collected ground-water and surface-water quality and water-level data from October 1998 through September 1999 at West Branch Canal Creek, Aberdeen Proving Ground, Maryland. The Canal Creek site is in northeast Maryland at the U.S. Army's Aberdeen Proving Ground in Edgewood, Maryland (fig. 1). The wetland study area is along West Branch Canal Creek (fig. 2).

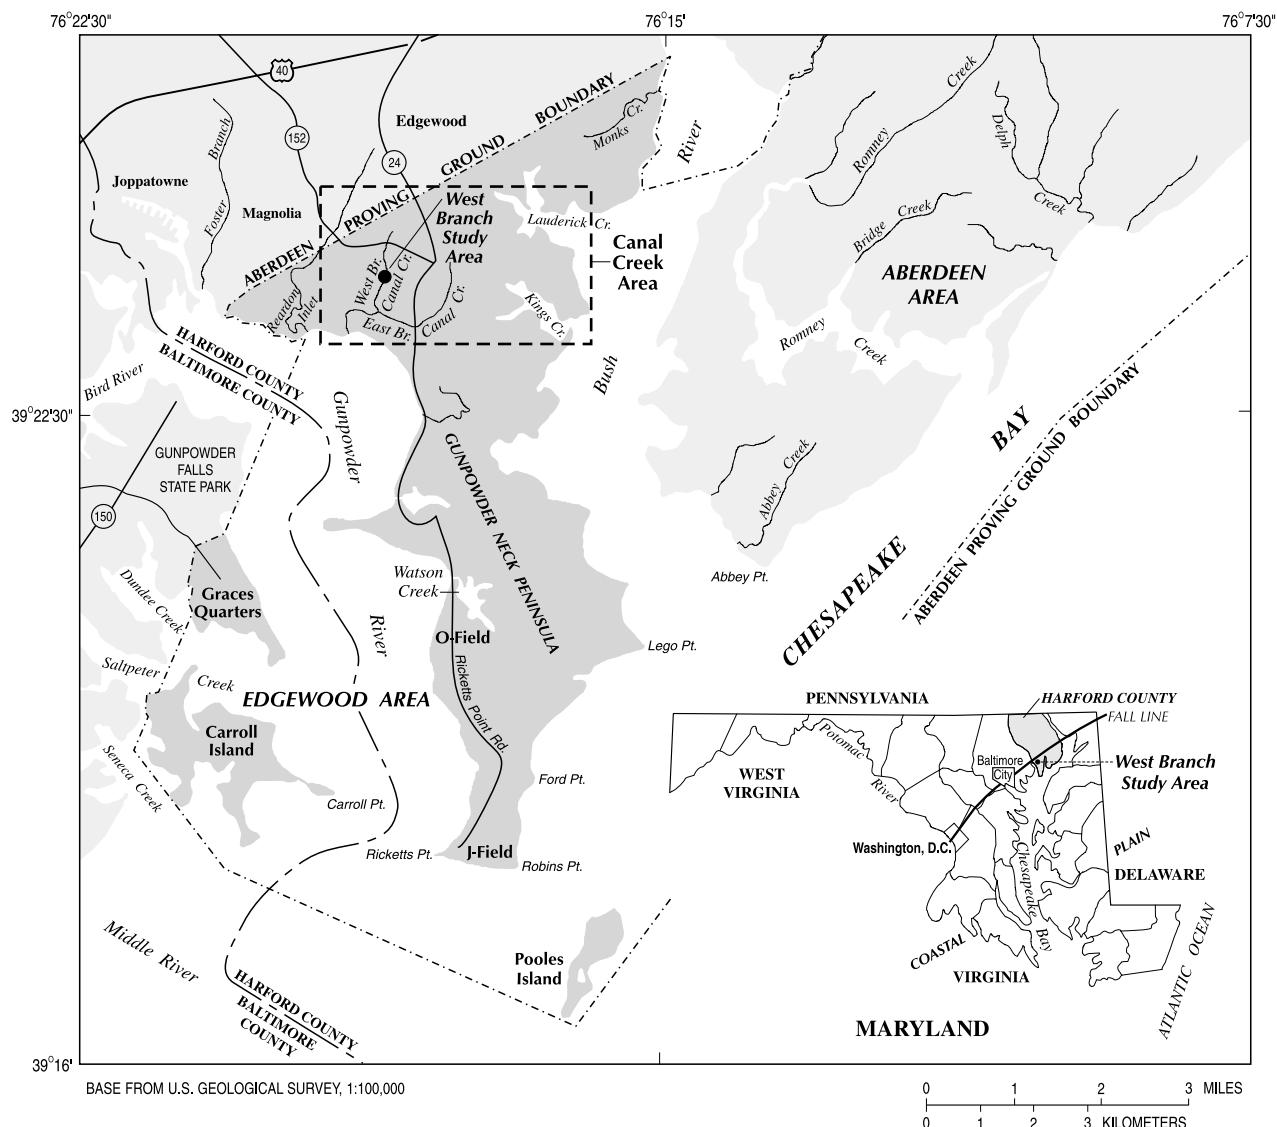

These data were collected in support of an ongoing USGS investigation of ground-water contamination in the wetland, including an evaluation of the factors controlling the fate and transport of the contaminants, and an analysis of natural attenuation as a possible remediation method. The primary contaminants in the study area are 1,1,2,2-tetrachloroethane, trichloroethene, carbon tetrachloride, chloroform, and their daughter products. Current investigations are focused on identifying natural attenuation processes in the freshwater tidal wetland and measuring the hydrologic, geochemical, and microbial processes affecting the contaminants, particularly chlorinated volatile organic compounds (VOCs).

### **Purpose and Scope**

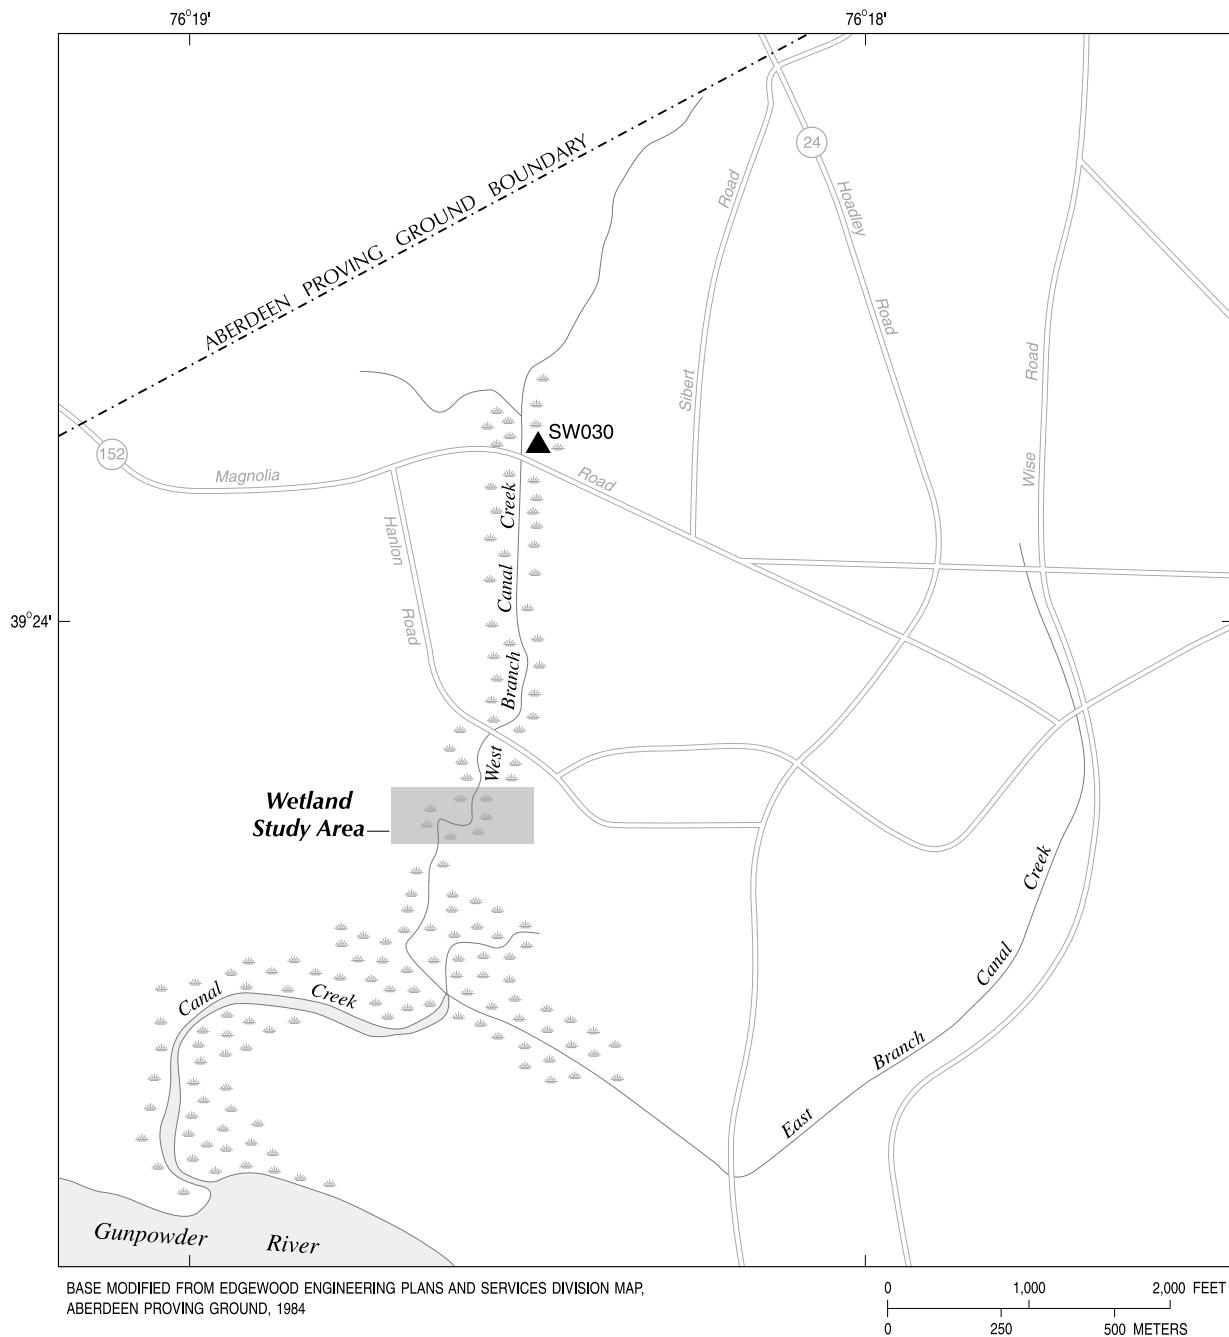

This report provides ground-water and surface-water data collected from October of 1998 through September of 1999, from a tidally influenced wetland under investigation for natural attenuation of VOCs. Methods for installation of piezometers and porous-membrane sampling devices (peepers) are presented. The report provides a description of the sample-collection and analysis methods. Quality-assurance data are also presented and evaluated.

### **Site History**

Aberdeen Proving Ground has been the U.S. Army's primary chemical warfare research and development center since 1917. West Branch Canal Creek was used as a disposal site for chlorinated solvents between World War I and the late 1970's. The chemical plant thought to be predominantly responsible for the contamination at the site has been inactive for more than 20 years and has recently been demolished. In 1990, the Comprehensive Environmental Response and Compensation Liability Act (CERCLA) placed Aberdeen Proving Ground on the National Priorities List. This action led to an Interagency Agreement between the U.S. Army and Region III of the U.S. Environmental Protection Agency that required investigation and remediation of the Canal Creek area.

**Figure 2.** Location of the wetland study area along West Branch Canal Creek, Aberdeen Proving Ground, Maryland, (modified from Lorah and Clark, 1996, p.106).

## Description of Study Area

The West Branch Canal Creek study site is in a wetland in the Edgewood area of Aberdeen Proving Ground. The creek is tidally influenced and drains southward into the Gunpowder River near the head of the Chesapeake Bay (fig. 1). Tides in the area range from 0.5 to 2.0 ft (feet). Average annual precipitation in the area for 1997, 1998, and 1999 was 39.8 in. (inches) (Charles Clough, Meteorology Team, Aberdeen Test Center, U.S. Army, written commun., 2000). The primary vegetation in the study area includes grasses, sedges, cattails, arrowhead, pickerelweed and *Phragmites*, a tall plant which is approximately 6 ft tall during the summer months (Durda and others, 1991, p. 2–4).

A thick deposit of unconsolidated Coastal Plain sediments underlies the Canal Creek area (Lorah and Clark, 1996). The wetland sediments consist of peat in the upper unit and clay, silt, sandy clay, and clayey sand in the lower unit. The Canal Creek aquifer, which is 30 to 70 ft thick in the study area, underlies the wetland sediments.

## Site Investigations

The USGS has participated in investigations of the Canal Creek area since 1985. Current investigations are focused on the processes of natural attenuation of contaminants in the freshwater tidal wetland, and measurement of the hydrologic and geochemical processes affecting the contaminants. Other goals of the current study include determining the extent of surface-water contamination in the wetland area, defining the fate and transport of the contaminants in the tidal wetland, and developing a solute-transport model for these contaminants. The data contained in this report support all of these efforts.

## Previous Investigations

A USGS investigation, which began in 1985, described contamination of ground water and surface water in the Canal Creek area (fig. 1), but did not include ground-water sampling within the wetland area (Lorah and Vroblesky, 1989). A follow-up study conducted by the USGS in 1992–1996 determined the distribution and the fate and transport of chlorinated VOCs in ground water within a relatively small area of the West Branch Canal Creek wetland (Lorah and others, 1997). This follow-up study defined the ground-water flowpaths and the contaminant concentrations along these flowpaths. Major geochemical and microbial processes active in the study area were identified, and an initial evaluation of the natural attenuation of contaminants was provided. Data collected from the West Branch Canal Creek wetland area between 1992–1996 were presented in Olsen and others (1997), and the evaluation of natural attenuation of chlorinated VOCs was presented in Lorah and others (1997).

## Current Investigations

The current investigation is focused on further defining the significant hydrologic, geochemical, and microbial processes affecting the natural attenuation of contaminants within the ground water, surface water, and wetland sediments. The USGS maintains 207 wells and piezometers

in the wetland area. These include two 4-in. diameter wells, seventeen 2-in. diameter piezometers, eighty-nine 0.75-in. drive-point piezometers, two 0.25-in. flexible-tubing piezometers, and ninety-seven 0.25-in. inverted-screen piezometers. In addition to the network of piezometers, the USGS periodically installs porous-membrane sampling devices to collect pore-water samples at selected locations.

The ground-water quality data in this report were obtained from samples collected from selected piezometers and peepers that were used from November 1998 through September 1999. Ground-water levels were measured periodically from October 1998 through May 1999. Surface-water samples were also collected from five locations from February through August of 1999.

## Acknowledgments

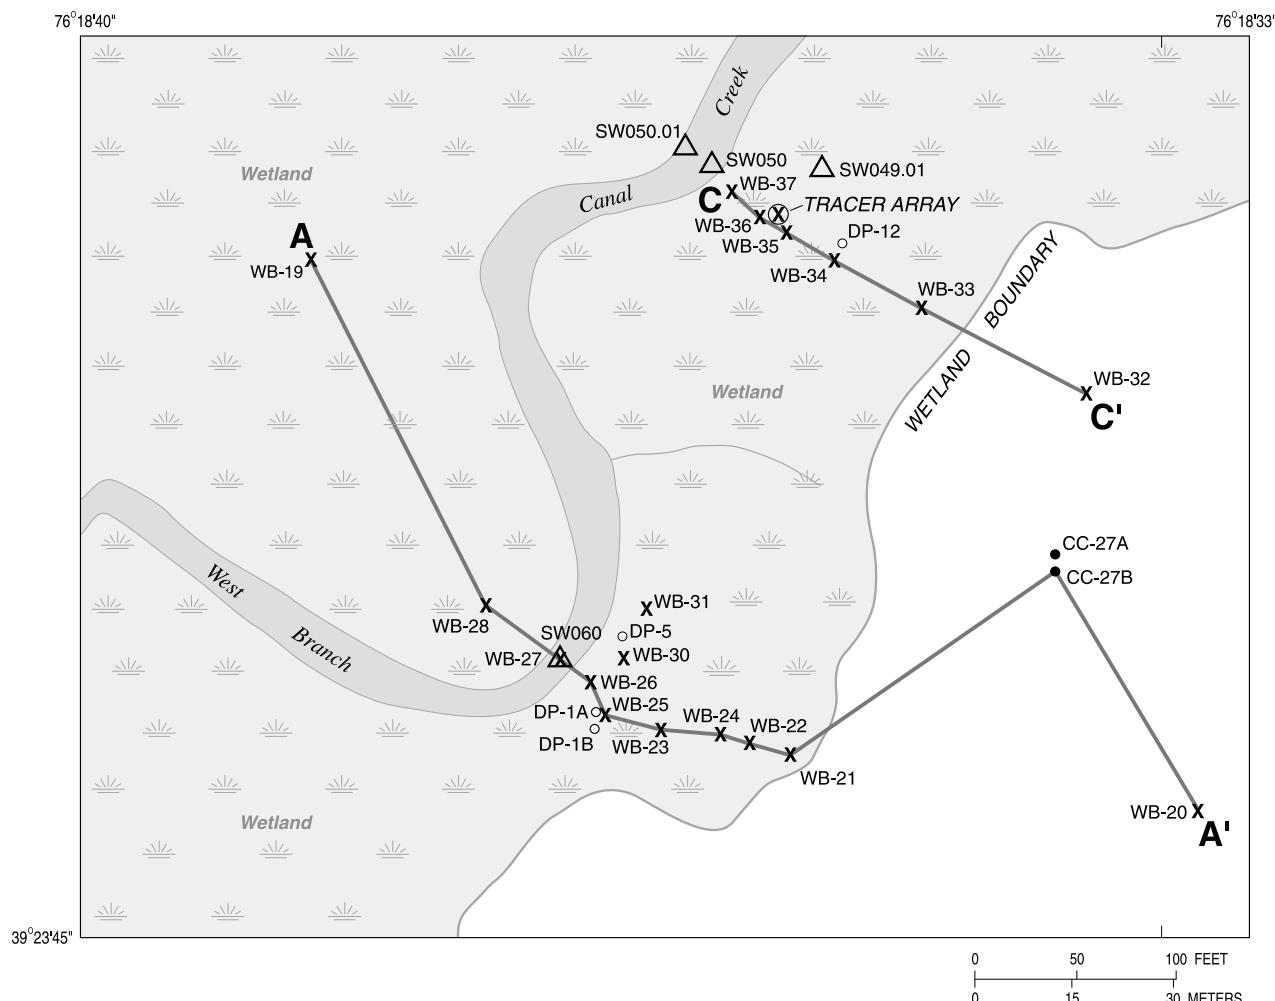

The authors thank the following people and agencies for their contributions to this study. John Wrobel, U.S. Army Environmental Conservation and Restoration Division and Allison O'Brien, contractor for the U.S. Army Environmental Conservation and Restoration Division, are thanked for their support throughout this project. Peter Pritchard of the U.S. Army Aberdeen Test Center is thanked for his ongoing efforts in maintaining the floating walkways and the bridge within the study site. Alan Rosencrance, Henry Gardner, and Thomas Shedd of the U.S. Army Center for Environmental Health Research, Fort Detrick, Maryland, have assisted the project for many years by maintaining the analytical chemistry equipment and on-site laboratory facility. The following personnel in the USGS Maryland-Delaware-D.C. District have also helped in the data-collection process: Daniel J. Phelan, Michael P. Senus, Linda J. Dyer, Elizabeth H. Marchand, and Glenn E. Miller, Jr. Finally, the Publications Unit of the Maryland-Delaware-D.C. District of the USGS is thanked for their assistance in the preparation of this report.

## Methods of Investigation

The Canal Creek sampling network includes ground-water and surface-water sampling locations. The ground-water samples were collected from 4-in. wells, 0.75-in. drive-point piezometers, 0.25-in. flexible-tubing piezometers, and 0.25-in. inverted-screen piezometers. Ground-water samples were also collected from peepers. Water-level data were collected from all three types of piezometers and from 2-in. wells installed for a previous investigation. Surface-water samples were collected at four locations in the creek and at one location in the wetland. Sampling locations are shown in figures 2 and 3.

### Ground-Water and Surface-Water Sampling Networks

Ground-water samples were obtained from 4-in. wells, 0.75-in. drive-point piezometers, 0.25-in. flexible-tubing piezometers, 0.25-in. inverted-screen piezometers, and

porous-membrane sampling devices. Surface-water samples were collected at five sites throughout the year. Surface-water sites on West Branch Canal Creek are near the stream-gaging station at Magnolia Road (SW030), which is shown on figure 2. Other surface-water sites are shown on figure 3, and include SW050, near the end of the C–C' transect and SW060, near the bridge on the A–A' transect.

**Piezometer Network** Three types of piezometers were sampled for the current investigation: 0.75-in. drive-point piezometers, 0.25-in. flexible-tubing piezometers, and 0.25-in. inverted-screen piezometers. All but two of the piezometers on transects A–A' and C–C' are 0.75-in. drive-point piezometers. Two 0.25-in. flexible-tubing piezometers were installed at site WB33 on the C–C' transect in 1998. The 0.25-in. inverted-screen piezometers were installed between sites WB35 and WB36 along the C–C' transect as part of a ground-water tracer test that was conducted from July 1998 through September 1999. These piezometers were sampled for water-quality parameters for the current investigation. A list of sampling locations including site name, hydrogeologic unit, well diameter, depths of screened interval, and land-surface elevation is provided in Appendix A at the end of the report.

**0.75-Inch Drive-Point Piezometers**—Ground-water samples were collected from selected nests of 0.75-in. drive-point piezometers that were installed between July 1994 and February 1995. The 0.75-in. drive-point piezometers were used to obtain ground-water samples for analysis of water-quality parameters, including organic and inorganic constituents, and reduction-oxidation (redox) constituents. The 0.75-in. drive-point piezometers were installed in nests of 5 to 10 piezometers along the A–A' and C–C' transects, which are generally aligned parallel to the ground-water flowpaths. The piezometers were constructed with a 0.5-in. inner Teflon-lined polyethylene tube that extends to the top of the screened interval. The transect locations are shown in figure 3. In each nest, the piezometers are arranged in a counter-clockwise direction, generally beginning with the shallowest and ending with the deepest. Each piezometer casing is 0.75-in.-diameter stainless steel, and each piezometer has a Solinst stainless-steel 6-in. screen, with a mesh size of 150 µm (micrometers). The depth intervals are identified by alphanumeric codes. The letter “A” corresponds to the shallowest, the letter “B” corresponds to the next shallowest, and so forth. For example, sample WB30A-1 was collected from nest location WB30, piezometer A (the shallowest piezometer in this nest), and was the first sample withdrawn because it is designated by “-1”. Sample WB30A-2 is a replicate sample of WB30A-1.

**0.25-Inch Piezometers**—Two types of 0.25-in. piezometers were sampled from February through September 1999. Two 0.25-in. flexible-tubing piezometers were installed in 1998 at site WB33, WB33Y, and WB33Z. The ground-water tracer array, which was constructed in the fall of 1998, contained ninety-seven 0.25-in. inverted-screen piezometers made of rigid stainless-steel tubing. The tracer array (figs. 4A and 4B) was installed in the upper peat unit of the wetland

sediment between piezometer sites WB35 and WB36 on the C–C' transect (fig. 3).

The two 0.25-in. flexible-tubing piezometers WB33Y and WB33Z were constructed of 0.25-in.-diameter Teflon tubes with a 1-in.-long screen at the end. The screens were made of stainless steel and brass with a quick-connect adapter that attached to the tubing without threads or adhesives. The screen mesh has a 40-micron diameter. Each screen was surrounded by a 2-in.<sup>3</sup> (cubic-inch) pack of fine-grained sand to prevent clogging of the screen. The sand pack was secured around the screen with an untreated, washed cotton sack that was cinched to the top of the screen with nylon cable ties. These piezometers were used to minimize disruption of the sediment. They were easy to install manually in shallow marsh sediments, and the screens were an inexpensive alternative to the 0.75-in. Solinst screen piezometers.

The 0.25-in. inverted-screen piezometers in the tracer array were installed to measure ground-water-flow rates and to monitor the effects of contaminant dispersion due to tidal fluctuations through the wetland sediments. The 0.25-in.-diameter piezometers were installed from 6 to 60 in. below land surface in a circular array within a 24-in. radius (fig. 4B). The piezometers were installed at 6- to 10-in. intervals. The piezometers were made of 0.25-in. stainless steel tubing with a 3-in.-long internal screen made of 100-mesh stainless steel. The screen is inverted and is contained inside the stainless-steel tubing so that water is drawn into the piezometer from a very small, discrete area near the opening of the tube. The screen orientation is important to the design of the tracer array. The inverted screen allows a sample to be withdrawn from that exact location without pulling water from the adjacent piezometers.

The 0.25-in. inverted-screen piezometers are named on the basis of their relative locations. Piezometers 6 in. below land surface begin with the letter “A”. Piezometers 12 in. below land surface begin with the letter “B”, and so on, down to 60 in. below land surface, which is designated with the letter “J” (table 1). The first two numerical characters represent the distance in inches from the center of the array, which was the tracer injection point. The last three numerical characters represent the position within the circular array, in degrees, increasing clockwise and beginning with 000 at the point closest to the stream. For example, sample H07–133 is located at a depth of 48 in. (H), 7 in. from the center of the array (07), and 133 degrees clockwise from the point closest to the stream (133). Selected 0.25-in. inverted-screen piezometers from the tracer array were sampled for VOCs in three sampling rounds during 1999. Seventeen piezometers were sampled in February through March, 20 were sampled in May, and 34 were sampled in September of that year.

**Porous-Membrane Sampling Devices (Peepers)** The peeper is a ground-water sampling tool used to gather discrete water-quality samples over a vertical section. The original device was designed by Hesslein (1976) for the study of lake-bottom sediments. The peepers are constructed of Lexan, a plastic product, in three sections (fig. 5). The first section is the main body of the peeper, and the remaining two sections are the side panels, which secure sheets of porous membrane over the sampling chambers. The main body of the peeper is 0.6 in. thick and 24 in. long, with 2 rows of 21 sampling chambers. Each side panel is 0.12 in. thick, with 2 rows of 21 windows, which allows solutes to diffuse from the surrounding pore water and through the membrane into the sampling chambers that are initially filled with deionized water. Before a peeper was installed, it was placed in a large tub of deionized water and purged with nitrogen gas overnight to remove oxygen from the water within the sample chambers.

The peepers were manually pushed vertically downward into the wetland sediment until the top of the first row of sampling chambers was level with land surface. The peepers were installed adjacent to existing wells or piezometers. The peepers were left to equilibrate with the ambient ground water for 2 to 3 weeks before the chambers were sampled and the contents analyzed.

Four peepers were installed, removed, and sampled during sampling rounds in November 1998, February, May, and August 1999. Each peeper location was named according to the well nearest the installation point. A "P" at the beginning of the sample name denotes peeper samples. For example, sample P12-14-1 was collected from peeper number 12 installed near well location DP-12, cell 14 down from the top (handle), first sample; P12-14-2 is the duplicate sample from the adjacent sample chamber.

**Surface-Water Sites** Surface-water samples were collected at five locations throughout the year. During very low tide, a seep was observed near the C-C' transect and was sampled (SW049.01). In addition to the West Branch Canal Creek surface-water locations (table 2), samples were collected at wetland seeps during very low tide. Another seep that was black was observed directly across from the end of the C-C' transect (SW050.01). A map of the surface-water sampling site locations is shown in figures 2 and 3.

#### Ground-Water and Surface-Water Sampling Methods

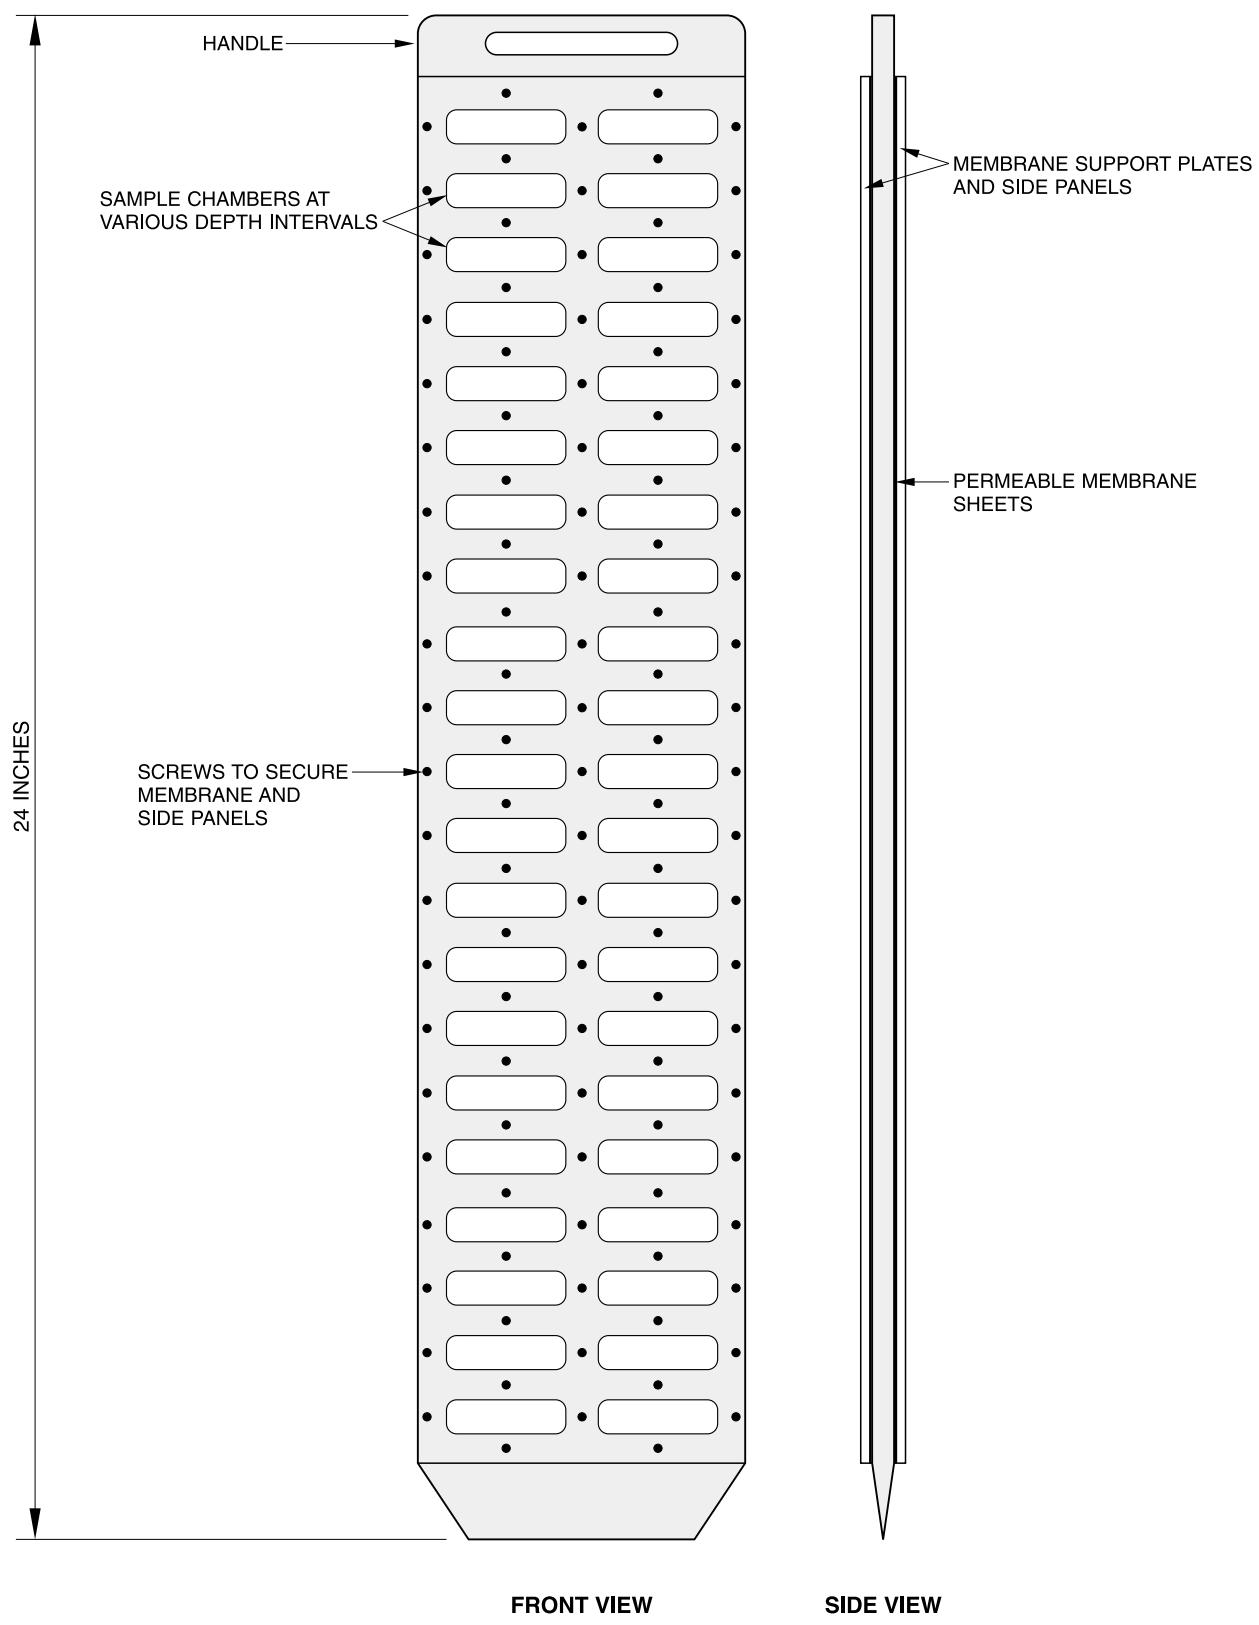

Ground-water samples were collected during three sampling rounds for piezometers and four sampling rounds for peepers. Surface-water samples were also collected during some ground-water sampling rounds. Samples were

collected and analyzed for field parameters, redox constituents, inorganic constituents, and organic constituents.

**Piezometer Sampling Methods** Three types of piezometers were sampled and the results are presented in this report. These include 0.75-in. drive-point piezometers, 0.25-in. inverted-screen piezometers, and 0.25-in. flexible-tubing piezometers. Methods of sampling varied throughout the year, depending on water availability, piezometer depth, and piezometer volume, and included a submersible pump, a peristaltic pump, a glass syringe with Teflon tubing, and a stainless-steel bailer.

**0.75-Inch Drive-Point Piezometer Sampling Methods**—Before sampling, at least two piezometer volumes were purged from each of the 0.75-in. drive-point piezometers. Piezometers were purged by use of either a glass syringe with Teflon tubing, a stainless-steel bailer, or a peristaltic pump if the piezometer produced sufficient volumes of water. The majority of the piezometers at the study site have low recovery rates and were purged using a stainless-steel bailer or a glass syringe with Teflon tubing. Piezometer recovery after purging typically took from several hours to several days before sampling could begin. After recovery, the water samples were collected using a peristaltic pump or a glass syringe with Teflon tubing assembled with a three-way stopcock valve between the syringe and tubing. This assembly allowed several milliliters of water to be expelled before sample collection and allowed water samples to be collected into sample vials with minimal aeration of the sample or the water column. Sampling rounds for the 0.75-in. drive-point piezometers took place in March, May through June, and July through August of 1999.

**0.25-Inch Piezometer Sampling Methods**—Sampling methods for the 0.25-in. inverted-screen piezometers and 0.25-in. flexible tubing piezometers were similar to the methods described in the 0.75-in. drive-point piezometer section. Due to low recovery rates and small water-column volumes, these piezometers were initially purged using a glass syringe and Teflon tubing. After recovery, samples were collected directly above the piezometer screen using the glass syringe and Teflon tubing assembled with a three-way stopcock valve. The 0.25-in. inverted-screen piezometers were sampled in February–March, May, and September of 1999. The 0.25-in. flexible-tubing piezometers were sampled in March, May, and August of 1999.

**Figure 5.** Schematic diagram of a porous-membrane sampling device.

**Table 2.** Surface-water location names and descriptions at West Branch Canal Creek

Location name	Location description
SW030	Stream-gaging station at Magnolia Road
SW049.01	Seep north of C-C' transect
SW050	End of C-C' transect
SW050.01	Seep west of C-C' transect
SW060	Walk bridge at A-A' transect

**Porous-Membrane Sampling Device (Pepper) Sampling**

**Methods** After the peepers were assembled and installed in the wetland sediments, they were left to equilibrate with ambient ground water for 2 to 3 weeks. When the peepers were removed, they were sampled immediately for sulfide, ferrous and ferric iron, methane, and VOCs. Samples were collected from the individual chambers of the peeper by puncturing the porous membrane and immediately withdrawing the sample water using a glass syringe and rigid Teflon tubing. Each peeper sample chamber yielded 11 mL (milliliters) of pore water. The sample was then expelled into sample vials with a smooth motion to minimize aeration. The peepers were constructed with two sample chambers at each depth interval; therefore, duplicates of some constituents could be collected at many of the depth intervals. Peepers were installed during sampling rounds in November of 1998, and February, May, and August of 1999.

**Surface-Water Sampling Methods** The surface-water samples were obtained using a grab method. Sample vials were submerged 3 to 5 in. below the water surface. The vials were quickly capped underwater to prevent sample aeration.

**Ground-Water and Surface-Water Analytical Methods**

Ground-water and surface-water samples were collected and analyzed from October 1998 through September 1999 for several field parameters, redox constituents, inorganic constituents, and organic constituents. Ground-water samples were analyzed in the field for specific conductance, pH, temperature, and if sufficient water was available, dissolved oxygen and alkalinity. Ground-water samples were analyzed at the on-site laboratory at West Branch Canal Creek for redox constituents and organic constituents. All inorganic analyses were conducted at the U.S. Geological Survey National Water-Quality Laboratory (NWQL) in Denver, Colorado. Surface-water samples were only analyzed for organic constituents at the on-site laboratory.

**Field Measurements** Parameters measured in the field included specific conductance, pH, water temperature, dissolved oxygen, and alkalinity. Specific conductance was measured with a YSI Model 3000 Temperature-Level-Conductivity meter, which was calibrated daily with three conductance standard solutions of approximately 200  $\mu\text{S}/\text{cm}$  (microsiemens per centimeter), 500  $\mu\text{S}/\text{cm}$ , and

1,000  $\mu\text{S}/\text{cm}$ . An Orion 290A meter with a gel-filled, temperature-compensated probe was used to measure pH. The pH meter was calibrated daily with two pH standards. Meter calibration was also verified against an additional standard. Water temperature was measured with the Orion 290A pH meter with a gel-filled, temperature-compensated probe or the YSI Model 3000 Temperature-Level-Conductivity meter. The piezometers often did not produce enough water to measure all of the field parameters. If there was sufficient water available, dissolved oxygen was measured using a modified Winkler titration method, and alkalinity was measured in the field after the sample had been filtered through a 0.45- $\mu\text{m}$  (micrometer) filter. Alkalinity as bicarbonate was determined using the inflection-point titration method.

**Redox Analyses** Redox-sensitive constituents that were analyzed include sulfide, ferrous and ferric iron, and methane. The samples were chilled until processed, and were analyzed at the on-site laboratory at West Branch Canal Creek.

Sulfide was measured in the field with a CHEMetrics A-1051 photometer kit using USEPA Method 376.2. The kit includes a portable spectrophotometer set to 670 nm (nanometers) that was calibrated daily, and Vacu-Vials with reagent. For each analysis, 25 mL of the sample water was acidified with three drops of a ferric chloride, hexahydrate, and hydrochloric acid mixture. Next, the sample was stirred with a Vacu-Vial filled with a reagent mixture of *N,N*-Dimethyl-*p*-phenylene diamine oxalate, isopropyl alcohol, hydrochloric acid, and deionized water. After stirring, the ampule tip was broken while submersed in the sample, allowing the sample water to be drawn up by vacuum into the reagent-filled Vacu-Vial. The vial of sample water and reagent were then allowed to react and equilibrate for 5 minutes before being placed into the spectrophotometer for analysis.

Ferrous and ferric iron samples were filtered through a 0.2- $\mu\text{m}$  filter and preserved with reagents in the field. The iron samples were processed at the on-site laboratory with a Bausch & Lomb Spectronic 21 spectrophotometer at 520 nm, using the colorimetric bipyridine technique described by Brown and others (1970) and Baedecker and

Cozzarelli (1992). After establishing an initial calibration curve, the instrument calibration was verified daily by processing several iron standards and plotting them on the calibration curve to verify accuracy. Ferric-iron concentrations were calculated by subtracting the ferrous-iron-concentrations from the total-iron concentrations.

Methane samples were collected and injected by syringe into sealed serum vials, which had been preserved with mercuric chloride and purged with nitrogen gas prior to sample collection. Methane samples were analyzed using a gas chromatograph with a flame-ionization detector. The instrument calibration was verified daily using standard compressed gases before and after sample analysis. Air blanks were analyzed frequently to verify the absence of biases due to contamination from the sample vials or the laboratory equipment. Nearly all methane samples from piezometers were collected in duplicate. The detection level of the instrument depended on the volume of the sample and the volume of the vial and ranged from 55 µg/L (micrograms per liter) to 133 µg/L for samples listed in this report. This method of methane analysis is described by Baedecker and Cozzarelli (1992).

**Inorganic Analyses** The USGS NWQL in Denver, Colorado performed the inorganic analyses. Inorganic samples were chilled immediately after collection and during shipment to NWQL. Samples were analyzed for calcium, magnesium, sodium, potassium, chloride, sulfate, fluoride, silica, iron, and manganese. Methods used by NWQL for analysis of inorganic constituents in water samples are explained in detail in Fishman and Friedman (1989), and in Fishman (1993).

**Organic Analyses** VOC analyses were performed at the on-site laboratory at West Branch Canal Creek. Samples were analyzed for VOCs using a purge-and-trap capillary gas chromatograph with a mass-selective detector. The analytical method used to analyze for the VOCs is equivalent to USEPA method 524.2, and is presented in Rose and Schroeder (1995). The lower calibration (detection) limit for the VOC analyses ranged from 0.5 to 2.0 µg/L. The higher calibration (detection) limit for the VOC analyses ranged from 200 to 250 µg/L.

### Water-Level Measurement Methods

Ground-water-level measurements were conducted during October and November 1998, and February and May 1999. Water levels were measured in 4-in. wells, 2-in. piezometers, and 0.75-in. drive-point piezometers. The ground-water measurements were made using a steel tape held at a reference point at the top of the well casing. All water-level data (Appendix F) have been adjusted to the land-surface elevation in feet above or below sea level, and adjusted for the height of the reference point. Occasionally, the measured ground-water levels are not consistent with the lunar tidal pattern. Factors that may affect the magnitude of the tidal impact on ground-water levels include the distance from the measuring point to the creek, the hydraulic conductivity of the sediments, the wind direction and velocity, and ice formation on Canal Creek or on the Gunpowder River.

### Quality-Assurance Methods

Quality assurance is tested for both the field and analytical procedures. Collecting replicate samples and wash-blank samples tests quality assurance in the field. Analytical quality assurance is tested at the on-site laboratory by evaluating the internal standard and surrogate responses, and by analyzing blind samples.

Replicate sample pairs were collected and analyzed, and then classified as one of three types of sample pairs: (1) replicate pairs in which both samples were below the lower detection limit; (2) replicate pairs in which one sample was above the lower detection limit and the other was below the detection limit; and (3) replicate pairs in which both samples were above the lower detection limit. The variability between samples in replicate pairs with two detections above the limit (classification 3), was determined by calculating the percent relative standard deviation (%RSD) of the concentrations of each analyte using the following formula:

$$\%RSD = SD/x$$

where:

- $\%RSD$  is the percent relative standard deviation;
- $SD$  is the standard deviation of the replicate analyses; and
- $x$  is the mean concentration of the replicate analyses.

The %RSD can be used to identify sources of variability among replicate samples, including variability introduced during the sampling process and intrinsic variability in the analytical method. The spatial and temporal differences in the composition of ground water or surface water were minimized by collecting samples at the same time, and sequentially in the same location.

In addition to sequential replicates, wash-blank samples were routinely collected and analyzed. These blank samples were collected in the field by processing analyte-free water using the same sampling methods and equipment used for the collection of field samples. The wash blanks were then analyzed, and if no analytes were detected, the cleaning and sampling procedures were not thought to affect sample contamination. If the blanks were analyzed and analytes were detected, then steps were isolated in the cleaning and sampling procedures to improve methods and therefore reduce the amount of contaminant carry-over from one sample to the next sample.

As part of the on-site laboratory's internal quality assurance and quality control (QA/QC), internal standards and surrogate standards were injected into every blank and sample. The injection of internal standards was necessary to determine the relative response of each target compound. Concentrations of the target compounds were calculated based on their responses relative to internal standards of known concentrations. The surrogate standards with similar properties to the analytes of interest were used to track possible variations in each analytical sample run. The

surrogate concentrations were known values; therefore, the responses of the surrogates could be evaluated to detect variations in instrument performance. If a sample was processed and either the internal standard response was low or the surrogate detection was inconsistent with the expected concentration, then the sample was reprocessed and/or the instrument was adjusted and re-calibrated before other samples were processed.

Another analytical quality-assurance method used was the analysis of blind samples. Blind samples are samples that were collected by field personnel from a site in replicate. The field personnel labeled one sample with the correct site identification and labeled the other sample with a "dummy" or "blind" sample location. After the samples were analyzed, the data were compared for variability.

## Sampling and Quality-Assurance Data

Ground-water samples were collected from 4-in. wells, piezometers, and peepers. Ground-water samples were analyzed for field parameters, redox constituents, inorganic and organic constituents. Surface-water samples were collected from five sampling sites and analyzed for organic constituents. Sequential replicate samples and wash blank samples were collected and analyzed during the entire sampling period.

### Ground-Water Data from Wells and Piezometers

Ground-water data were collected from wells and 0.75-in. piezometers during sampling rounds in March, May through June, and July through August 1999. These data are presented in Appendixes B, D, and E1.

Replicate samples, blind samples, and wash-blank samples were processed to detect variability and bias in the sampling and analytical processes.

**Field Measurements and Redox Constituents for Well and Piezometer Samples** Samples from 87 piezometers were collected and analyzed for field parameters (specific conductance, pH, air temperature, water temperature, dissolved oxygen, bicarbonate, and alkalinity) and redox constituents (sulfide, iron, and methane) during sampling rounds in March, May, June, July, and August of 1999 (Appendix B). Seventy-one replicate methane samples were collected and analyzed during these three sampling rounds. The 71 replicate methane samples were classified into three categories. Classification 1 represents replicate samples that were analyzed below the detection limit. Classification 2 represents replicate samples with 1 sample detected above the lower detection limit and 1 sample detected below the detection limit. Classification 3 represents samples that were analyzed with both samples having detections above the lower detection limit. Of the 71 replicate methane samples, 37 replicate samples were in classification 1; 3 replicate samples were in classification 2; and 31 replicate samples were in classification 3. The minimum %RSD for classification 3 was 0.05, the maximum %RSD was 75.72,

and the median %RSD for the replicate methane analyses was 3.2. Wash blanks and blind samples were not analyzed for these constituents.

### Inorganic Constituents for Well and Piezometer Samples

Inorganic constituents were analyzed for 37 piezometer samples. Three replicate samples were collected for inorganic constituents; one was a blind sample. A blind blank sample was also collected. Inorganic piezometer data are presented in Appendix D.

A listing of compounds that were detected in the three replicate piezometer samples and their %RSD is presented in table 3.

The median %RSDs for replicate analyses of inorganic constituents were less than 16; therefore, sample variability for inorganic constituents is considered low. The parameter with the greatest median %RSD was dissolved potassium (15.7), and dissolved iron exhibited the largest maximum %RSD (114.1). The variability in potassium and iron could be due to the small sample set. The wash blank contained 0.1 mg/L (milligrams per liter) of chloride, but otherwise was analyte-free.

### Organic Constituents for Well and Piezometer Samples

Ground-water samples were collected from 4-in. wells, 0.25-in., and 0.75-in. piezometers for VOC analysis at the on-site laboratory at West Branch Canal Creek. The 0.25-in. piezometers were sampled in February, March, May, and September 1999. The 0.75-in. piezometers and 4-in. wells were sampled in March, May, June, July, and August 1999. The well and piezometer data for organic analysis are presented in Appendix E1. Of the 64 compounds analyzed, 37 were not detected above the lower detection limits (0.5 µg/L – 2.0 µg/L) for well and piezometer ground-water analyses, and are listed at the top of page 13.

Ground-water samples were collected from 207 wells and piezometers from February through September of 1999, including 63 replicate samples, 3 triplicate samples, 2 quadruplicate samples, and 15 wash-blank samples. Of the 63 replicate samples, 7 were reprocessed because 1 of the 2 samples failed internal QA/QC criteria. Of the 15 wash blanks collected, 1 failed internal QA/QC criteria and 3 replicate samples were processed. Results of analyses for organic constituents in ground-water samples collected from wells and piezometers are presented in Appendix E1.

Relative standard deviations for 14 compounds that were detected in well, piezometer, and wash-blank replicate samples are presented in table 4.

Bromomethane and benzene both have relatively high median %RSDs compared to the other organic compounds. The %RSD for bromomethane may be attributed to possible laboratory contamination; this compound is frequently detected with higher than normal concentrations in calibration standards. The other organic compound median %RSDs are all below 30, and half are below 18. This overall increased variability compared to the %RSD of inorganic constituents may be due to the volatility of the compounds being analyzed. VOC concentrations in samples

*Organic constituents that were not detected in well and piezometer samples*

Bromobenzene	Bromoform	<i>n</i> -Butylbenzene
<i>sec</i> -Butylbenzene	<i>tert</i> -Butylbenzene	Chlorobenzene
2-Chlorotoluene	4-Chlorotoluene	1,2-Dibromo-3-chloropropane

Benzene	1	47.1	47.1	47.1

can be negatively affected if a sample is aerated during sample collection or during the transfer of the sample from the vial to the instrument for analysis.

Of the 15 wash blanks analyzed, 3 contained detections. Both wash blanks collected on March 12, 1999, contained detections. The first March 1999 wash blank contained 12.3 µg/L of 1,1,2,2-tetrachloroethane, 3.8 µg/L of trichloroethene, 6.6 µg/L of chloroform, and 1.0 µg/L of bromomethane. The second March 1999 wash blank contained 34.6 µg/L of 1,1,2,2-tetrachloroethane, 14.6 µg/L of trichloroethene, 14.0 µg/L of carbon tetrachloride, 30.3 µg/L of chloroform, and 3.0 µg/L of methylene

chloride. The third wash blank collected on September 2, 1999, contained 1.34 µg/L of trichlorofluoromethane.

The two wash blanks collected in March 1999 were believed to have been contaminated from environmental sources. The cleaning procedures were evaluated and no other wash blanks collected after this time period contained environmental contamination. The wash blank collected in September 1999 was contaminated from a refrigerant that accumulated in the internal standard, which was injected into the sample when analyzed. The internal standard was replaced and no other wash blanks were contaminated.

## **Ground-Water Porous-Membrane Sampling Device (Peeper) Data**

Ground-water samples were collected from peepers during November 1998, and February, May, and August 1999. Peeper samples were analyzed for redox constituents (Appendix C) and organic constituents (Appendix E2). Replicate samples were collected from peeper devices, but wash-blank samples were not collected because of the sampling technique.

### **Redox Parameters for Porous-Membrane Sampling Devices (Peepers)**

Redox constituents were analyzed for 345 peeper samples from November 1998 through August 1999. Sulfide analyses included four replicate pairs. Of these, three pairs had no deviation between the two samples and one pair had a 28.3 %RSD. Iron was detected in one replicate pair with a 5.2 %RSD. Methane analyses included 24 replicate pairs (Appendix C). The methane results are presented in table 5, according to peeper location. Peeper P19 had the lowest median %RSD (1.4). Peeper P12 had the greatest median %RSD (2.3). The replicate peeper

samples have a very low median %RSD for methane.

### **Organic Constituents for Porous-Membrane Sampling Devices (Peepers)**

Peeper samples were collected during November 1998, February, May, and August 1999, and analyzed for 64 organic constituents. Of the 362 peeper samples collected, 33 replicate sample pairs were processed to calculate variability. Duplicate samples were processed for 29 samples because the initial sample failed laboratory internal QA/QC criteria. Organic peeper data are shown in Appendix E2.

Of the 64 VOC compounds, 39 were not detected above the lower detection limit (0.5 µg/L – 2 µg/L) in any of the samples. These compounds are therefore not listed in Appendix E2. Chloroform data are not shown in Appendix E2 because only one sample contained chloroform (sample P12-12 was collected on August 4, 1999, and contained 4.7 µg/L of chloroform).

The compounds that were not detected above the lower detection limit are listed below.

Bromobenzene	Bromochloromethane	Bromodichloromethane
Bromoform	<i>n</i> -Butylbenzene	<i>sec</i> -Butylbenzene
<i>tert</i> -Butylbenzene	Carbon tetrachloride	Chlorobenzene
Chloroform	2-Chlorotoluene	4-Chlorotoluene
1,2-Dibromoethane	Dibromochloromethane	Dibromomethane
1,2-Dichlorobenzene	1,3-Dichlorobenzene	1,4-Dichlorobenzene
1,1-Dichloroethane	1,1-Dichloropropane	1,2-Dichloropropane
1,3-Dichloropropane	2,2-Dichloropropane	<i>cis</i> -1,3-Dichloropropene
<i>trans</i> -1,3-Dichloropropene	Ethyl benzene	Isopropylbenzene
<i>p</i> -Isopropylbenzene	Naphthalene	<i>n</i> -Propylbenzene
Styrene	Tetrachloroethene	1,2,3-Trichlorobenzene
1,2,4-Trichlorobenzene	1,1,1-Trichloroethane	1,2,4-Trimethylbenzene
1,3,5-Trimethylbenzene	<i>m,p</i> -Xylene	<i>o</i> -Xylene

**Table 5.** Replicate porous-membrane sampling device analyses for methane

[%RSD, percent relative standard deviation]

Peeker	Number of replicate pairs with detections	Minimum %RSD	Maximum %RSD	Median %RSD
P12	7	1.2	115.8	2.3
P19	7	0	4.5	1.4
P35	10	0.3	64.7	1.9

**Table 6.** Replicate porous-membrane sampling device analyses for organic constituents

[%RSD, percent relative standard deviation]

Compounds detected	Number of replicate pairs with detections	Minimum %RSD	Maximum %RSD	Median %RSD
1,1,2-Trichloroethane	3	9.1	39.7	37.3
1,2-Trichloroethane	4	1.4	56.7	36.0
Trichloroethene	3	10.2	19.1	11.8
<i>cis</i> -1,2-Trichloroethene	22	0.3	87.2	14.5
<i>trans</i> -1,2-Trichloroethene	16	2.3	90.8	16.0
Vinyl chloride	25	2.0	107.8	26.7
Bromomethane	6	1.4	72.5	23.9
Trichlorofluoromethane	1	3.8	3.8	3.8
Toluene	1	90.1	90.1	90.1

One pair of replicate peeper samples that were analyzed for VOCs had no detections in either sample. Additional replicate pairs that had detections were used to assess variability. Relative standard deviations for replicate analyses of VOCs in peeper samples are presented in table 6.

Toluene had the highest median %RSD (90.1). Vinyl chloride had the largest range between the minimum %RSD (2.0) and the maximum %RSD (107.8). Vinyl chloride is one of the target compounds in this study; it has a low molecular weight and is also very volatile, which may explain the high variability. The organic data from the peepers appear to be more variable than organic data from the wells and piezometers. Both the sampling techniques used to obtain the peeper samples and the very small 11-mL volume of sample water from the peepers may result in higher variability.

#### Surface-Water Sampling Data

Surface-water samples were collected at five locations from February through August of 1999. All 16 samples were analyzed for VOCs, and 1 sample was analyzed for field parameters. The sample that was analyzed for field parameters had a specific conductance of 554 µS/cm and a pH of 6.38. Organic surface-water data are presented in Appendix E3.

Of the 16 samples, 4 were replicate pairs. Relative standard deviations for replicate analyses of VOCs in surface-water samples are presented in table 7.

Concentrations of VOCs in surface-water samples ranged from below the detection limit to 22.1 µg/L for chloroform, which was detected at site SW060 on August 3, 1999. The most frequently detected VOC was

**Table 7.** Replicate surface-water sample analyses for organic constituents

[%RSD, percent relative standard deviation; na, not applicable]

Compounds detected	Number of replicate pairs with detections	Minimum %RSD	Maximum %RSD	Median %RSD
1,1,2,2-Tetrachloroethane	2	5.8	81.1	na
1,1,2-Trichloroethane	1	3.0	3.0	3.0
Trichloroethene	1	80.9	80.9	80.9
Carbon tetrachloride	2	1.2	17.1	na
Chloroform	2	4.8	6.4	na

1,1,2,2-tetrachloroethane, which was detected in 15 of 16 samples. The maximum concentration of 1,1,2,2-tetrachloroethane was 18.5 µg/L, which was detected in a sample collected on February 18, 1999, from site SW049.01. The next most frequently detected VOC was carbon tetrachloride, which was detected in 12 samples, followed by chloroform, which was detected in 10 samples.

#### Water-Level Data

Water-level measurements were collected in October and November 1998, and February and May 1999. Water-level data were collected from 105 locations, including 2-in. wells, 4-in. wells, and 0.75-in. drive-point piezometers. Data were generally collected at high tide, low tide, and occasionally during mid-tide. The water-level data were used to estimate ground-water flux rates. These data were also collected to assist in the development of a ground-water-flow and solute-transport model. Water-level measurements, screen depth, and hydrogeologic unit information are presented in Appendix F.

#### Summary

This report presents water-quality and water-level data collected by the U.S. Geological Survey from October 1998 through September 1999 at West Branch Canal Creek, Aberdeen Proving Ground, Maryland. The water-quality data were collected from ground-water and surface-water sites. This report also includes a description of the sampling and analytical methods, and an evaluation of the quality-assurance data.

Ground-water samples were collected from wells and 0.75-inch drive-point piezometers during March, May, June, July, and August 1999. Samples from 0.25-inch inverted-screen piezometers were collected during February, March, May, and September 1999. Samples from 0.25-inch flexible-tubing piezometers were collected during March,

May, and August 1999. Ground-water samples were analyzed for field parameters, redox constituents, inorganic constituents, and organic constituents. Quality-assurance data for inorganic constituents indicate that for well and piezometer sampling techniques, the variability is low. Quality-assurance data for organic constituents indicate that there is increased variability, which may be due to the volatility of the compounds being analyzed. Wash-blank and blind samples indicate that both sampling procedures and analytical techniques do not typically contribute to contamination of the samples from wells and piezometers.

Porous-membrane sampling devices (peepers) were installed in November 1998, and February, May, and August 1999. Peepers were sampled for sulfide, ferrous and ferric iron, methane, and organic constituents. Replicate samples analyzed for sulfide, iron, and methane indicate low variability in all analyses. Replicate samples collected from peepers and analyzed for organic constituents indicate higher variability than in well and piezometer samples. The increased variability may be due to the sampling techniques used to obtain the peeper samples, and the high volatility of the compounds being analyzed.

Surface-water samples were collected in 1999, and analyzed for organic constituents only. The variability in these samples was high. The variability in the surface-water samples may be due to changing environmental conditions and the volatility of the compounds being analyzed. The most frequently detected organic constituent was 1,1,2,2-tetrachloroethane. Water-level measurements were made in October and November 1998, and February and May 1999.

**Appendix A. Sampling locations in the West Branch Canal Creek study area,  
Aberdeen Proving Ground, Maryland**

[Site identification number represents the latitude, longitude, and piezometer number within the cluster and is used for tracking water-quality samples; \*, site was used to measure water levels only, no water-quality samples were collected; --, no data; pressure transducers were installed in wells ending in ".1"]

Well no.	Site identification no.	Hydrogeologic unit	Well diameter (inches)	Screened interval (feet below land surface)	Land surface elevation (feet above sea level)
CC-27A	392343076183301	Canal Creek aquifer	4.0	18.0 - 23.0	11.2
CC-27B	392343076183302	Canal Creek aquifer	4.0	35.0 - 40.0	11.4
DP-12	392348076183401	Wetland sediments	2.0	2.6 - 3.6	1.05
DP-1A	392346076183501	Wetland sediments, upper peat unit	2.0	1.9 - 2.9	1.20
DP-1B	392346076183502	Wetland sediments, lower clayey unit	2.0	6.5 - 7.5	1.23
DP-5	392346076183503	Wetland sediments	2.0	3.7 - 4.7	1.36
